Editorial Comment: New Insights on the Mechanisms Affecting Fertility in Men with Non-Seminoma Testicular Cancer before Cancer Therapy

In this paper, Tania Dias and colleagues, try to compare the sperm proteome of patients with NSTC, who cryopreserved their sperm before starting cancer treatment, with that from healthy fertile men.

Because patients with non-seminoma testicular cancer (NSTC) cancer can be subfertile or infertile, and present reduced sperm quality and the underlying mechanisms are unknown, this paper may help to identify the underlie causes involved with this condition.

The authors collected Semen samples after 2 to 3 days of abstinence and evaluated Volume, sperm motility, and sperm concentration according to World Health Organization (WHO) 2010 guidelines. Semen samples were then cryopreserved in TEST-yolk buffer and stored in liquid nitrogen at -196°C.

The identification of the differentially expressed proteins (DEPs) between the control and NSTC groups was conducted via Scaffold software. (Proteome Software Inc., Portland, OR, USA)

The criteria for the selection of DEPs for validation by Western blot (WB) included: 1) proteins involved in reproductive system development and function; 2) proteins involved in the top canonical pathways; 3) proteins with a higher difference of abundance between the experimental groups; 4) proteins with a well-described function in the literature.

The authors identified 189 differentially expressed proteins (DEPs) in the dataset, from which five DEPs related to sperm function and fertilization were selected for validation by Western blot.
And they indentified that underexpression of the mitochondrial complex subunits NADH:Ubiquinone Oxidoreductase Core Subunit S1 (NDUFS1) and ubiquinol-cytochrome C reductase core protein 2 (UQCRC2), as well as the underexpression of the testis-specific sodium/potassium-transporting ATPase subunit alpha-4 (ATP1A4) in the NSTC group.

The results indicate that sperm mitochondrial dysfunction may explain the observed decrease in sperm concentration, total sperm count and total motile count in NSTC patients. The identified DEPs may serve as potential biomarkers for the pathophysiology of subfertility/infertility in patients with NSTC.
